

For every $\mu \in \Gamma$, if ζ is Dirac atomic measure over μ then $F(\zeta, \mu) \geq 1 - \epsilon$ since T accepts data generating process in Γ with probability $1 - \epsilon$. Therefore it follows from (8) that for every $\delta > 0$ there exists $\zeta \in \Delta(\Gamma)$ such that $\min_{\mu} F(\zeta, \mu) > 1 - (\epsilon + \delta)$, i.e., that T is $(\epsilon + \delta)$ -manipulable.
